

Can tailored interventions increase mammography use among HMO women?

Answer (EN)

The provided excerpt does not report study outcomes, so it cannot confirm whether the tailored interventions increased mammography use. The text only establishes the research design: a three-year randomized field trial that compared tailored telephone counseling and tailored print materials against “a high-quality usual care system” among 1,099 women aged 50 and older recruited from a health maintenance organization (HMO). The excerpt frames the research question — “Compared to usual care, is tailored telephone counseling more effective than tailored print materials for promoting mammography screening?” (arXiv:SciQ:ctx) —but contains no results, effect sizes, or conclusions about screening rates. No fact in the supplied text supports or refutes an increase in mammography use; any answer about efficacy would be invention, not evidence.
